In this paper, it is proved that the maximal violation of Mermin’s inequalities of \( n \) qubits occurs only for GHZ’s states and the states obtained from them by local unitary transformations. The key point of our argument involved here is by using the certain algebraic properties that Pauli’s matrices satisfy, which is based on the determination of local spin observables of the associated Bell-Mermin operators.

The Bell inequality [1] was originally designed to rule out various kinds of local hidden variable theories. Precisely, the Bell inequality indicates that certain statistical correlations predicted by quantum mechanics for measurements on two-qubit ensembles cannot be understood within a realistic picture based on Einstein, Podolsky, and Rosen’s (EPR’s) notion of local realism [2]. However, Bell-type inequalities also provide tests to distinguish entangled from nonentangled quantum states. For example, Gisin’s theorem [3] asserts that all entangled two-qubit states violate the Clauser-Horne-Shimony-Holt (CHSH) inequality [4] for some choice of spin observables, that is, the violation of the CHSH inequality characterizes entangled states of two qubits.

As is well known, maximally entangled states, such as Bell states and GHZ states [5], have become a key concept in the nowadays quantum mechanics. On the other hand, from a practical point of view maximally entangled states have found numerous applications in quantum information [6]. A natural question is then how to characterize maximally entangled states. There are extensive earlier works on maximally entangled states [7], however, this problem is far from being completely understood today. It is argued that the maximal violation of the Bell-type inequalities can be used to characterize maximally entangled states [8]. Therefore, for characterizing maximally entangled states, it is suitable to study the states that maximally violate the Bell-type inequalities. Recently, the author [9] has completely resolved the two-qubit case and shown that the Bell states and the states obtained from them by local unitary transformations are the unique states that violate maximally Mermin’s inequalities.

The techniques involved here are introduced by the author [9] and based on the determination of local spin observables of the associated Bell operator. We show that a Bell-Mermin operator presents a maximal violation on a state if and only if the associated local spin observables satisfy the certain algebraic identities that Pauli’s matrices satisfy. Consequently, we can find those states that show maximal violation, which are just the states obtained from the GHZ states by local unitary transformations. Our method involved here is simpler (and more powerful) than one used in [12], which is based on the determination of the eigenvectors and eigenvalues of the associated Bell operator. We have illustrated the three-qubit case in [9] and shown that all states that maximally violate the Bell-Klyshko inequality [13] are exactly GHZ states and the states obtained from them by local unitary transformations, which was conjectured by Gisin and Bechmann-Pasquinucci [8].

Let us give a brief review of Mermin’s inequality of \( n \) qubits. Let \( A_{j}, A'_{j} \) denote two spin observables on the \( j \)th qubit, \( j = 1, ..., n \). Define the Bell-Mermin operator as following

\[
\mathcal{M}_{n} = \frac{1}{27} \left( \bigotimes_{j=1}^{n} (A_{j} + iA'_{j}) - \bigotimes_{j=1}^{n} (A_{j} - iA'_{j}) \right).
\]  

(1)

It is easy to check that

\[
\mathcal{M}_{n} = A'_{1}A_{2} \cdots A_{n} + A_{1}A'_{2}A_{3} \cdots A_{n} + \cdots - A'_{1}A'_{2}A'_{3}A_{4} \cdots A_{n} - A'_{1}A_{2}A_{3}A'_{4} \cdots A_{n} - \cdots + A'_{1}A'_{2}A_{5} \cdots A_{n} + \cdots
\]

\[
\vdots
\]

(2)

where each line of Eq.(2) contains all distinct permutations of the subscripts that give distinct products. Since the total number of terms in Eq.(2) is \( \sum_{j \text{ odd}}^{(n)} = 2^{n-1} \),

*Electronic address: zqchen@wipm.ac.cn
it concludes that
\[ ||\mathcal{M}_n|| \leq 2^{n-1}. \] (3)

However, assuming “local realism” [2] one concludes by using Mermin’s elegant technique [11] that for \( n \) even,
\[ ||\mathcal{M}_n|| \leq 2^{n/2}, \] (4)
and
\[ ||\mathcal{M}_n|| \leq 2^{(n-1)/2}, \] (5)
when \( n \) is odd, respectively. The inequalities appearing in Eqs.(4) and (5) are said to be Mermin’s inequalities. The
original Mermin’s inequality is the case that \( A_j = \sigma^j_+ \) and \( A'_j = \sigma^j_- \). Clearly, for \( n = 2 \) there is no violation of
Mermin’s inequalities for the prediction that quantum mechanics makes. However, for \( n \geq 3 \) Mermin [11] showed that the prediction \( 2^{n-1} \) that quantum mechanics makes for the GHZ state
\[ |GHZ\rangle = \frac{1}{\sqrt{2}} (|0\cdots 0\rangle + i|1\cdots 1\rangle), \] (6)
maximally violates the original Mermin’s inequality by an exponentially large factor of \( 2^{(n-2)/2} \) for \( n \) even or
\( 2^{(n-1)/2} \) for \( n \) odd. This is the first spectacular demonstration of the fact that there is no limit to the amount
by which the quantum-mechanical correlations can exceed the limits imposed by Bell-type inequalities.

In the sequel, we always assume \( n \geq 3 \). The main result we shall prove is that

**Theorem:** A state \( |\varphi\rangle \) of \( n \) qubits maximally violates Eq.(4) for \( n \) even or Eq.(5) for \( n \) odd, that is,
\[ \langle \varphi | \mathcal{M}_n | \varphi \rangle = 2^{n-1}, \] (7)
if and only if it can be obtained by a local unitary transformation of the GHZ state \( |GHZ\rangle \), i.e.,
\[ |\varphi\rangle = U_1 \otimes \cdots \otimes U_n |GHZ\rangle \] (8)
for some \( n \) unitary operators \( U_1, \ldots, U_n \) on \( \mathbb{C}^2 \).

The sufficiency of **Theorem** is clear. Indeed, as shown by Mermin [11], the GHZ state \( |GHZ\rangle \) satisfies Eq.(7)
with \( A_j = \sigma^j_+ \) and \( A'_j = \sigma^j_- \). For generic states \( |\varphi\rangle \) of the form Eq.(8), they maximally violate Mermin’s inequality of \( n \) qubits with
\[ A_j = U_j \sigma^j_+ U_j^* \quad \text{and} \quad A'_j = U_j \sigma^j_- U_j^*, \]
where \( U_j^* \) is the adjoint operator of \( U_j \).

It remains to prove the necessity. Since
\[ \mathcal{M}_3 = A'_1 A_2 A_3 + A_1 A'_2 A_3 + A_1 A_2 A'_3 - A'_1 A'_2 A'_3 \] (9)
coincides with the Bell-Hardy-Klyshko operator [13], the three-qubit case has been proved by the author [9]. The
key point of our argument involved in [9] is by using the certain algebraic properties that Pauli’s matrices satisfy,
which is based on the determination of local spin observables of the associated Bell operator. As follows, by using
this method we show that every state \( |\varphi\rangle \) satisfying Eq.(7) can be obtained by a local unitary transformation of
the GHZ state \( |GHZ\rangle \).

Let us fix some notation. For \( A_j^{(\varphi)} = \vec{a}_j^{(\varphi)} \cdot \vec{\sigma}_j \) \( (1 \leq j \leq n) \), we write
\[ (A_j, A'_j) = (\vec{a}_j, \vec{a}'_j), \quad A_j \times A'_j = (\vec{a}_j \times \vec{a}'_j) \cdot \vec{\sigma}_j. \]
Here \( \vec{\sigma}_j \) is the Pauli matrices for the \( j \)th qubit; the norms of real vectors \( \vec{a}_j^{(\varphi)} \) in \( \mathbb{R}^3 \) are equal to 1. Clearly,
\[ A_j A'_j = (A_j, A'_j) + iA_j \times A'_j, \] (10)
\[ A'_j A_j = (A_j, A'_j) - iA_j \times A'_j, \] (11)
and
\[ ||A_j \times A'_j||^2 = 1 - (A_j, A'_j)^2. \] (12)

We always write
\[ A''_j = A_j \times A'_j. \] (13)

By Eqs.(10), (11) and (13), one has that
\[ [A_j, A'_j] = 2iA''_j \quad \{A_j, A'_j\} = 2(A_j, A'_j) \] (14)
where \( [A_j, A'_j] \) and \( \{A_j, A'_j\} \) are the commutator and anticommutator of the spin observables \( A_j \) and \( A'_j \),
respectively.

As follows, we write \( A''_j, A''_{j_2}, \ldots, \) etc., as shorthand for
\[ I \otimes \cdots \otimes I \otimes A''_{j_1} \otimes I \otimes \cdots \otimes I \otimes A''_{j_2} \otimes I \cdots \otimes I, \]
where \( I \) is the identity on a qubit. The proof of **Theorem** for necessity consists of the following three steps:

(i) At first, we show that if \( ||\mathcal{M}_n|| = 2^{2(n-1)} \) for \( n \geq 3 \), then
\[ (A_j, A'_j) = 0 \] (15)
for all \( j = 1, \ldots, n \).

We need to distinguish between the cases of \( n \) odd and \( n \) even. For \( n \) odd \( (n \geq 3) \), the square of the Bell-
Mermin’s operator Eq.(2) is that
\[ M_{2n}^2 = \sum_{k=0}^{(n-1)/2} (-1)^k 2^{n-2k-1} \sum_{1 \leq j_1 < j_2 < \cdots < j_{2k} \leq n} \left[ A_{j_1}, A'_{j_1} \right] \left[ A_{j_2}, A'_{j_2} \right] \cdots \left[ A_{j_{2k}}, A'_{j_{2k}} \right], \]

where \( \{j_1, j_2, \ldots, j_{n-1}\} \) is a set of \( n-1 \) indices each of which runs from 1 to \( n \). Hence, by Eq.(14) one has that
\[ M_{2n}^2 = 2^{n-1} \sum_{k=0}^{(n-1)/2} \left( \sum_{1 \leq j_1 < j_2 < \cdots < j_{2k} \leq n} A''_{j_1} A''_{j_2} \cdots A''_{j_{2k}} \right). \] (16)

Analogously, for \( n \) even \( (n \geq 4) \) one has that
\[ M_{2n}^2 = 2^{n-1/2} \sum_{k=0}^{n/2} \left( \sum_{1 \leq j_1 < j_2 < \cdots < j_{2k} \leq n} A''_{j_1} A''_{j_2} \cdots A''_{j_{2k}} \right) - (-1)^{n/2} 2^{n-1} (A_1, A'_1)(A_2, A'_2) \cdots (A_n, A'_n). \] (17)

Since \( \sum_{k=0}^{(n-1)/2} = 2^{n-1} \), it immediately concludes from Eqs.(12) and (16) that if \( \|M_{2n}^2\| = 2^{(n-1)} \) for \( n \geq 3 \) odd, then Eq.(15) holds true for all \( j = 1, \ldots, n \). Also, for \( n \) even \( (n \geq 4) \), by Eqs.(12) and (17) one has that
\[ \|M_{2n}^2\| \leq 2^{n-1} \left( 1 - (-1)^{n/2} x_1 \cdots x_n + \sum_{k=1}^{n/2} \sum_{1 \leq j_1 < j_2 < \cdots < j_{2k} \leq n} \sqrt{1 - x_{j_1}^2} \cdots (1 - x_{j_{2k}}^2) \right). \]

where \( x_j = (A_j, A'_j) \) for \( j = 1, \ldots, n \). It is easy to check that when \(-1 \leq x_j \leq 1 \) for \( j = 1, \ldots, n \), the function in the right hand of the above inequality attains the maximal value \( 2^{2(n-1)} \) only at \( x_1 = \cdots = x_n = 0 \). This concludes Eq.(15).

In particular, if Eq.(15) holds true, it concludes that
\[ A_j A'_j = -A'_j A_j = iA''_j, \] (18)
\[ A'_j A''_j = -A''_j A'_j = iA_j, \] (19)
\[ A''_j A_j = -A_j A''_j = iA'_j, \] (20)
\[ A''_j = (A'_j)^2 = (A''_j)^2 = 1, \] (21)
i.e., \( \{A_j, A'_j, A''_j\} \) satisfy the algebraic identities that Pauli’s matrices satisfy [14]. Therefore, by choosing \( A''_j \)-representation \( \{0\}_j, \{1\}_j \), i.e.,
\[ A''_j |0\>_j = |0\>_j, A''_j |1\>_j = -|1\>_j, \] (22)
we have that
\[ A_j |0\>_j = e^{-i\alpha_j} |1\>_j, A_j |1\>_j = e^{i\alpha_j} |0\>_j, \] (23)
\[ A'_j |0\>_j = i e^{-i\alpha_j} |1\>_j, A'_j |1\>_j = -i e^{i\alpha_j} |0\>_j, \] (24)
for some \( 0 \leq \alpha_j \leq 2\pi \). We write \(|0\cdots0\>_n\), etc., as shorthand for \(|0\>_1 \otimes \cdots \otimes |0\>_n\). Then, \( \{\epsilon_1, \ldots, \epsilon_n: \epsilon_1, \ldots, \epsilon_n = 0, 1\} \) is an orthogonal basis of the \( n \)-qubit system.

(ii) Secondly, we prove that for \( n \geq 3 \), a state \( |\varphi\rangle \) of \( n \) qubits satisfying
\[ M_{2n}^2|\varphi\rangle = 2^{(n-1)} |\varphi\rangle \] (25)
must be of the form
\[ |\varphi\rangle = a |0\cdots0\>_n + b |1\cdots1\>_n, \] (26)
where \(|a|^2 + |b|^2 = 1\).

In this case, \( \|M_{2n}^2\| = 2^{2(n-1)} \) and hence Eq.(15) holds. By Step (i), we can uniquely write
\[ |\varphi\rangle = \sum_{\epsilon_1, \ldots, \epsilon_n = 0, 1} \lambda_{\epsilon_1, \ldots, \epsilon_n} |\epsilon_1 \cdots \epsilon_n\>_n, \]
where \( \sum_{\epsilon_1, \ldots, \epsilon_n = 0, 1} \lambda_{\epsilon_1, \ldots, \epsilon_n} = 1 \). In particular, by Eq.(16) and (17) we have that
\[ A''_{j_1} A''_{j_2} \cdots A''_{j_{2k}} |\varphi\rangle = |\varphi\rangle \] (27)
where \( 1 \leq j_1 < j_2 < \cdots < j_{2k} \leq n \). By Eq.(22) we conclude from Eq.(27) that \( \lambda_{\epsilon_1, \ldots, \epsilon_n} = 0 \) whenever \( \{\epsilon_{j_1}, \epsilon_{j_2}, \ldots, \epsilon_{j_{2k}}\} \) contains odd number of 1. Therefore, besides \( \lambda_{0,0, \ldots, 0} \) and \( \lambda_{1,1, \ldots, 1} \), one has that \( \lambda_{\epsilon_1, \ldots, \epsilon_n} = 0 \). This concludes Eq.(26) with \( a = \lambda_{0,0, \ldots, 0} \) and \( b = \lambda_{1,1, \ldots, 1} \).

(iii) Finally, we prove that if a state \( |\varphi\rangle \) of \( n \) qubits with \( n \geq 3 \) satisfies Eq.(7), then
\[ |\varphi\rangle = \frac{1}{\sqrt{2}} (e^{i\theta} |0\cdots0\>_n + e^{i\theta} |1\cdots1\>_n), \] (28)
for some $0 \leq \phi, \theta \leq 2\pi$.

By Eq.(3), one concludes that Eq.(7) is equivalent to that $\mathcal{M}_n|\varphi\rangle = 2^n-1|\varphi\rangle$. In this case, $|\varphi\rangle$ satisfies Eq.(25) and hence is of the form Eq.(26). By using Eq.(2) we have that

$$A'_1 A_2 \cdots A_n |\varphi\rangle = |\varphi\rangle.$$  

Hence, by Eqs.(23) and (24) one has that

$$\text{iae}^{-i(a_1 + a_2 + \cdots + a_n)} = b,$$

that is, $|a| = |b| = \frac{1}{\sqrt{2}}$. Therefore, Eq.(28) holds true.

Now, denote by $V_j$ the unitary transform from the original $\sigma_j^z$-representation to $A_j^{\prime\prime}$-representation on the $j$th qubit, i.e., $V_j|0\rangle = |0\rangle_j$ and $V_j|1\rangle = |1\rangle_j$, and define

$$U_1 = V_1 \begin{pmatrix} e^{i\phi} & 0 \\ 0 & 1 \end{pmatrix}, U_2 = V_2 \begin{pmatrix} 1 & 0 \\ 0 & e^{i\theta} \end{pmatrix},$$

and $U_j = V_j$ for $3 \leq j \leq n$. Then $U_j$ are all unitary operators on $\mathbb{C}^2$ so that Eq.(8) holds true and the proof is complete.

In conclusion, by using some subtle mathematical techniques we have shown that the maximal violation of Mermin’s inequality of $n$ qubits only occurs for the states obtained from the GHZ states by local unitary transformations. The key point of our argument involved here is by using the certain algebraic properties that Pauli’s matrices satisfy, which is based on the determination of local spin observables of the associated Bell operator.

The method involved here is simpler (and more powerful) than one used in [12] and can be applied to the Bell-Klyshko inequality [9]. Note that both Mermin’s and Bell-Klyshko’s inequalities are special instances of all-multipartite Bell-correlation inequalities for two dichotomic observables per site derived by Werner-Wolf and Žukowski-Brukner [15]. This seems to suggest that the statement holds true for each of the Bell-correlation inequalities for two dichotomic observables per site. It is argued that maximally entangled states should maximally violate Bell-type inequalities [8] and all states obtained by local unitary transformations of a maximally entangled state are equally valid entangled states [16], we conclude that the Bell-correlation inequalities for two dichotomic observables per site characterize the GHZ states as maximally entangled states of $n$ qubits. Finally, we remark that the W state

$$|W\rangle = \frac{1}{\sqrt{n}}(|10\cdots0\rangle + |010\cdots0\rangle + \cdots + |0\cdots1\rangle)$$

cannot be obtained from the GHZ states by a local unitary transformation and hence does not maximally violate the Bell-correlation inequalities for two dichotomic observables per site whenever the above conjecture holds true, although it is a “maximally entangled” state in the sense described in [17]. Hence, from the point of view on the violation of EPR’s local realism, the W state might not be regarded as a “maximally entangled” state and we need some new ideas for clarity of the W state [18].
